## HEADQUARTERS, USS. ARMY DUGWAY PROVING GROUND

 DUGWAY UT 84022-5000April 14, 2010
ATTENTION OF:

## Office of the Command Judge Advocate

Mr. John Greenewald, Jr.

Dear Mr. Greenewald:
We previously advised that your request made under the provisions of the Freedom of Information Act (FOIA), 5 U.S.C. Section 552 was forwarded to our office as a matter under our purview. The document you requested was titled "Entomological Field Test Technology, Bellwether II, BIO 531." We advised you in a letter that the document was located in our Technical Library but that it was still classified at the Confidential level and would be withheld at that time under Exemption (b)(1) of the FOIA.

After considerable review, it has been determined that this document has been regraded to unclassified. It is now enclosed to fulfill your request.

All fees assessed to this point are less than the minimum charge.
If you have questions regarding this letter, please address them to Ms. Teresa S. Shinton, FOIA Officer, (435) 831-3333; email: teresa.shinton@us.army.mil.

Sincerely,

$\mathcal{H} \begin{aligned} & \text { Kateni T. Leakehe } \\ & \text { Major, U.S. Army } \\ & \text { Command Judge A }\end{aligned}$
Command Judge Advocate

## SECNET

## FOREWORD

(C) The U. S. Army Chemical Corps has been assigned the task of providing the Department of Defense with adequate CBR weaponry. Certain entomological veotor-agent systems, after a period of laboratory demonstrations, qualitative field experience, and theoretioal evaluations, have reached the quantitative field test stage and Dugway Proving Ground has been assigned the field testing responsibility. The present volume, containing the field experimentation of BELLWETHER -II, reports on the endeavors of Dugway Proving Ground to standardize an entomological field test technology.
(U) This material contains information affecting the national defence of the United States within the meaning of the Espionage Laws, Title 18, U.S.C., Sections 793 and 794, the transmission or revelation of which in any manner to an unauthorized person is prohibited by law.
(U) The authority for conducting this test is contained in Dugway Proving Ground Operating Program, FY 1962-1966, Target Year FY 1962, Appendix 1 to Annex C, Operating Schedule, Dugway Proving Ground, Utah, 1 July 1961, revised 1 October 1961. Secret. Tests were funded under Digway Proving Ground Job Order Numbers 1-02-10-1 and 1-02-10-2 in support of Department of the Army Research and Development Project Number 4D98-05-028-02.
(U) When this dooument has served its purpose, it should be destroyed. It should not be returned to the originating office.
(U) Reproduction of this document, in whole or part, is prohibited except with specific permission of the issuing office.

## DIGEST

(S) The objectives of BELLNHTHAR-II, using releases of uninfeoted, starved, virgin female Aedes aegypti mosquitoes, were, in part:

1. To evaluate the effeots of varying the host distance, the host concentration, and the vector/host ratio:
2. To determine the effect of the presence or absence of overt movement of the human samplers upon the outdoor biting rate; and
3. To investigate methods of placement of human samplers in open terrein and within built-up areas.
(U) Inherent throughout the entire test was the development and improvement of a basic entomological field test teohnology.
(C) A total of 14 field trials were conducted in the period extending from 6 September to 20 October 1960. Up to 100 assigned military personnel were used as samplers in each trial, and grid arrays involving dispersal distanoes muoh greater than those involved in BELLNETHRR-I were incorporated in this test design.
(S) From the data generated in this test, and under the specific conditions encountered, it is conoluded that:
4. In a 30 -minute sampling period, there was no significant difference in veotor biting aotivity at distances up to 100 feet from the release point, but maximum biting aotivity ocourred at distanoes of less than 200 feet.
5. Intervening hosts did not interfere with either the veotors' outward spread or biting aotivity.
6. No conclusive findings were generated as to the effect of host concentration.
7. When the number of vectors was increased by a factor of 10 , approximately 10 times as many bites were received and the proportion of hosts bitten was inoreased an average of 36 per cent.
8. Vector biting aotivity showed a tendenoy to be highest when the hosts were alternately in motion and then motionless for reourring 5 -minute periods, and to be lowest when the hosts moved continuously.
9. Hosts looated near buildings were subjeoted to significantly greater veotor biting activity than ware hosts located in open areas.
10. Veotors did not tend to distribute themselves evenly throughout an isolated built-up area, and, further, they did not tend to redistribute themselves evenly during the interims between host oocupations.
11. No oonclusive findings were generated as to the optimum sampling duration.
12. No evidenoe of orepusoular-period biting preferenoe was obtained in these trials.
13. No oomolusive findings were generated conoerning the average longevity of this species when exposed to ambient desert oonditions.

## INTRODUCTION

## BACKGROUND

(S) The U. S. Army Chemioal Corps Researoh and Development Command in June 1960 (1) directed Dugway Proving Ground (DPG), Utah, to investigate and develop entomologioal field testing teohniques designed to permit the quantitative evaluation of entomologioal munitions. These teohniques were required to be adequate for evaluating entomologioal weapon systems against strategio targets such as built-up areas of oities, industrial oenters, and logistioal oomplexes; jungles and heavily wooded aress containing dispersed enemy personnel; and any type of terrain containing well equipped and well organized guerrilla foroes. Of physioal necessity, the present test had to exolude the effects of oonfferous, deoiduous and rain forests, and of heavily built-up areas if it was to be oonduoted at DPG. Rather stringent time limitations preoluded oonduating these trials alsewhere and still utilize the autumn 1960 testing season.) Trials in the southern United States inoorporating these and other target aspeots are being considered for FY 1962.
(U) The general baokground and the problems assooiated with the development of an entomologioal field test technology have been adequately desoribed in DPGR 259, BELLNETHERR-I (2), and need not be repeated here. The basic problem of obtaining and evaluating valid, quantitative data gathered by relativels untrained, military personnel has not been completely resolved in the present test series. However, progress has been made, and, as a result, data should improve in the future.

## OBJECTIVES

(S) The speaifio objectives of this test, using releases of uninfected, starved, virgin femele Aedes aegypti mosquitoes, were:

1. To evaluate the offeots of varying the host distanoe, the host conoentration, and the veotor/host ratio (Phases B and C);
2. To determine the effect of the presence or absence of overt movement of the human samplers upon the outdoor biting rate of this mosquito (Phase D);
3. To investigate methods of placoment of human samplers in open terrain (Phases B and C) and within built-up areas (Phase E);
4. To determine the optimum sampling period duration (various pheses), and whether time of dey need be oonsidered (Phase $\mathbb{I}$ ); and
5. To determine the average longevity of the A. aegypti mosquito when exposed to ambient desert conditions (Phase F).
(J) Inherent throughout the entire test was the development and improvement of a basio entomological field test teohnology. This was to be aohieved in the various data phases, in observations of the conduot of the trials, and in evaluating the date recoived.

SCOPE
(C) This test, oomprising sir phases, was oonduoted in a series of orientation trials (Phase A), 14 field trials (Phases B through E), and 2 laboratory-soale trials (Phase $F$ ). The testing period began 29 August 1960 and extended to the effeotive end of the autumnal testing season, late Ootober 2960. For the conduct of this test, it was neoessary to orient and train a total of 100 military assignees. Together with the experience of using troops as sampling units on more oomplex grid arrangements, further basio data on the behavior of the A. aegypti mosquitin were also gained, as were guidelines for designing future field trials wherein different grid oonfigurations and terrain types would be used.

## MBTHODS AND MATERIALS

## THST SITH

(U) The possibility of veotor persistence within a trial area deoreed that several days elapse before a further trial be conduated in the partioular area of a previous trial. This faot neoessitated using several widely dispersed areas for the full oonduot of these trials. These areas, shown in Figure 1 , were the Clay Flats Targot, the region west of the West Gate, the vioinity of the road leading north from Baker Laboratory, seotions of the Downwind Grid, and in the built-up seotion of GPI-2. The Phase $F$ studies were conduoted just outside of Baker Laboratory.

## TEST VECTOR

(C) The test veotors were uninfeoted, virgin female CD strain A. aegypti mosquitoes, raised in the standard manner from egg papers furnished by the U. S. Army Chemical Corps Biologioal Leboratories (Biolabs), Fort Detrick, Frederick, Maryland. The mosquitoes were reared in the inseotary at Baker Laboratory; the sexes were separated in the pupal stage by means of a Biolabs pupal separator; and all the adults were 6 days or older and starved 16 to 24 hours prior to release when used.

Fig. 1. - Map showing test areas, Bio 531, BELLWETHER-II.
in BELLNETHER-I, were also used in BELLNETHER-II. The l-quart size was used for fills of up to 250 veotors and the l-gallon size was used for fills to 2500 vectors. In the 5000 -veotor releases of Phase $\mathbb{E}$, two lgallon fixtures were used (in the first Phase E trial, the l-gallon containers were not yet available, and, therefore, a 2-gallon 'hat box' was used). The cardboard tops of the ice cream oartons were pushed out and replaced by a small square of nylon bobbinet. The string harnesses used in BELLWETHER-I were replaced by reuseable wire and olip harnesses.
(v) Prefabricated test fixture stands were oonstruoted for this test, roplaoing the driven stakes used in BELLMETHER-I; one of these is shown in Figure 2. The use of this device also facilitated moving the fixtures to keep them upwind of the sampling array at function time in the Phase C trials.

SAMPLING PERSONNEL

## 

昔禜变。

station until the oompletion of the trial. In those trials where radio communication was required to synohronize the times of test fixture funotioning, the vehiole was driven a few hundred feet upwind and parked until the command to release was received. This was relajed to the test personnel and the vehicle was then driven rapidly upwind.

## TEST PROCEDURE BY PHASES

$(U)$ This test was conduoted in six phases--A through F.

## Phase A

(U) Phase A was a familiarization phase that followed the general orientation briefing. In this phase, in whioh several groups vere tested concurrently, each group oonsisted of 10 men positioned equidistantly around the perimeter of a oirole having a radius of 15 feet--in the manner of BELLWHTHAR-I. One hundred veotors were released in the center of each, oirole, and the men reoorded the number of bites and probes reoeived in a 20 -minute period. The purpose of this phase was to familiarize the men with the prooedures fo be used in the forthooming trials and with entering data on the data card (see Fig. 3). Severe reaotors were removed from the test series following Phase A.

## Subsequent Phases

$(U)$ The speoific methods followed in the various data phases ( $B$ through $F$ ) of this test are presented, precoding the statistical analysis of the results of each phase, in the Investigational Prooedures and Analyses seotion.

## MEIHOROLOGICAL PROCEDURES

(U) In all phases exoept $A$ and $F$, two 2-meter meteorological stations were used, and, wherever possible, these stations were located at least 0.25 mile upwind of the test site to reduce the possibility that these positions would serve as shelters to the inseots and thus bias the results. The locations of these stations are depiated in Figures 4 through 7. These stations recorded the 2-meter wind speed and direotion on chart rolls; the relative humidity, ground temperature, and ajr temperature were determined and manually reoorded at lo-minute intervals throughout eaoh trial. A devioe for determining inoident ultraviolet radiation was also utilized. On those trials oonducted within several miles of the West Gate, this devioe was installed at the West Gate and was operated from the line current available there. On the other trials, a separate generator was provided and the instrument was looated in the field at one of the meteorologioal stations. It reoorded all inoident ultraviolet radiation falling between 2000 and 3760 that struok an exposed hemisphere. However, no oorrelation between biting aotivity and ultraviolet radiation could be detected.

Pig. 3. - Date card used in the BrLL
(U) No meteorologioal ooverage was provided in the Phese a orientation trials. In Phase F, a 24 -hour recording hygrothermograph placed on the ground near the two groups of cones reoorded ambient temperature and relative humidity throughout the trial periods.

## PHOTOGRAPHIC PROCTDURES

(U) In order to produce a general orientation film for training personnel for biting rate assessment in future entomological field trials, a soenario of soene sequenoes was prepared. Photographio Sootion, Target Operations Branoh, photographed these various sequenoes on 16 -millimeter Kode ohrome film. The prooessed film was then roughly edited and stored. Further test sequences and seleoted seotions of a U. S. Public Health Servioe film will be obtained and inoorporated before final editing is attempted.

INVESTIGATIONAL PROCEDURES AND ANALYSES 250-foot oiroles. Simultaneously, 1000 veotors were released in the center of each of the separate oircles, and 3000 vectors were released in the center of the conoentric oonfiguration. Bites were then recorded by each of the hosts for six consecutive 5 -minute time periods so that there was a total of 600 host-time units. Therefore, the total number of bites recorded in a trial divided by 600 was the mean number of bites per host-time unit, the so-called average bite number.
(U) For every time-unit, ea oh of the six ciroles produced a number signifying the proportion of hosts on that oircle whose reported bites exoe日ded the average bite number. Thus, if the average bite number was

Fig. 4. - Grid array for Phase B, BELLWETHER-II.
14.9 and 10 of 25 hosts in a oircle reported 15 bites or more during a given time interval, the appropriate proportion for that time-oirole unit was 0.40. In this way, each trial produoed 36 proportions ( 6 timeunits $\times 6$ oiroles).
(U) An analysis of variance, based on the three-way cross olassifioation of time, radius, and type of oirole (individual versus concentrio), was performed on the proportions obtained in eaoh trial, weighting each proportion according to the number of hosts involved. The test of significance for each component was made in the analysis by means of the chi square ( $X^{2}$ ) distribution, where the sum of squares for each oomponent had first been converted to a chi square value by the formula:

$$
\frac{\text { sum of squares }}{\bar{T} \bar{q}}=X^{2}
$$

where $600 \overline{\mathrm{p}}$ equels the total number of host-time units over the entire trial with reported bites not less than the average bite number, and व equals 1 - $\bar{p} .1$ The results of these analyses are presented in Table 2.

[^0]TABLR 2: Results of the Chi Square Analysis, Trials B-1 through B-3, BILLITETHER-II, Bio 531 (CONFIDENITAL)

| $\mathrm{R} \times \mathrm{C} \times \mathrm{T}$ | 10 | 8.9 | 1.9 | 13.7 |

Statistioally signifioant at the 5.0 per cent level.
(U) As shown in Table 2, there was a tendency for every main effeot and the two-factor interaotion $\mathrm{R} \times \mathrm{C}$ to be statistically signifioant. The effects of these oomponents are, therefore, disoussed below.

## Effect of Radius and Type of Circle

(U) It proved diffioult in these trials to oompare biting aotivity on individual oiroles with that on oonoentrio oiroles, because. in the former, 1000 vectors were released in the oenter of each of three oiroles, while in the latter, 3000 veotors were released in the oenter of a single set of three oiroles. An alternate method, releasing 1000 vectors in all oases, might have been used. However, using that method, the veotor/host ratio in the separate oiroles would be three times the ratio in the ooncentrio oiroles, and this would not permit meaningful oomparisons. The present trials are well suited to oomparing the relative effeots of the different radil of oiroles and the different time periods, as well as the interaotions of these faotors with the "oirole-type" faotor.
(c) Interpratation of the $\mathrm{R} \times \mathrm{C}$ interaotion was oomplioated by the faot that there were three (1.e, more than two) different radii. Ignoring the 150 -foot oiroles, the effedt of "radius" was oonsidered by simply comparing the results from the 100 -foot oiroles with the results from the 250-foot oiroles (see Table 3). In every trial, signifioantly higher biting aotivity per host was found at the lo0-foot oirole than at the $250-$ foot circle. Further, there was a general tendenoy in all trials for the values from the l50-foot oiroles to fall below the values from the $100-$ foot oiroles. This suggests that optimum biting aotivity in the initial primary time period ( 30 minutes) ooourred at less than 150 feet, but this distance was doubtiessly affeoted by the wind speed. In addition, the "radial effeot" (100-foot aotivity)-(250-foot aotivity) for the concentrio oiroles was compared with the same offeot for the separate oiroles. No signifioant difference was deteoted in Trials B-1 and B-2, but the difference in Trial B-3 was signifioantly larger in the oonoentrio oiroles than in the separate oiroles. This may have resulted beoause of the peouliarly low biting aotivity observed on the 100 -foot

TABLE 3: Proportion of Hosts Exoe日ding the Average Bite Number, Summarized Over the Time Units and Segregated With Respeot to Radius and Type of Cirole, Trials B-1 through B-3, BELLWETHER-II, Bio 531 (CONFIDENTIAL)

separate oircle（0．45），and，since it was not demonstrated in Trials B－1 and B－2，the interpretation for this phase might be that，under the oon－ ditions encountered，the l50－foot oirole of hosts did not significantly interfere with the passage of veotors from the 100－100t to the 250－foot oirole．

## Refoot of Time

（c）As indioated by the results of the ohi square analysis in Table 2，there were significant differences in the proportions determined for the six time intervals in both Trials B－1 and B－3．The oomposite data presented in Table show that in both of these trials the propor－ tional value reached a maximum in the second time period（ $5-10$ minutes） and deolined thereafter．In oontrast，no signifioant difference oould be deteated in the proportions obtained for the six time intervals of Trial B－2．Thus，biting aotivity in this trial did not deorease with an increase of time，and，presumably，if the trial had been extended beyond the 30 －minute time period，a considerable number of additional bites would have been obtained．However，even within the 30 －minute sampling period， the average number of bites per vector（1．49）was greater than that ob－ tained in any other entomologioal field trial oonduoted at DPG．The preoise reason or reasons for the greatly enhanced results of this trial over all others oonduoted at DPG，however，oould not be asoertained．

PHASE C
（C）Phase C was oonduoted to examine three host－veotor relation－ ships，viz．：the host distance（the distance of the hosts from the veotor release），the host oonoentration（the number of hosts per unit area），and the veotor／host ratio（the number of veotors per host）． Eaoh of these relationships was evaluated at two levels－－an arbitrary high and a low．A total of 80 hosts were used in eaoh trial；and they were arraged along a orosswind line in eight 20 －foot squares，each 0.5 mile distant from the adjacent squares，as shown in Figure 5．The hosts were divided into four groups（A，B，C，and D），with eaoh group oompris－ ing two of the 20 －foot squares．In eaoh group，one of the squares oon－ tained 4 men with 1 man at eaoh oorner，and the other square contained 16 men spaoed 5 feet apart．These arrays represented the variation in host ooncentration at the arbitrary low and high levels，respeotively．
（U）In four of the eight squares，the veotor release points were located 20 feet upwind of the hosts；at the other four， 100 feet upwind． As such，they represented the arbitrary low and high level，respeotively， of host distance．The third variable studied，veotor／host ratio，was varied by using either a $10 \% 1$ or a 100／1 ratio release upwind of each 20 －foot square．The test fixtures were funotioned simultaneously upon a signal from the Test Officer，and sampling was oontinued for 30 minutes．
（U）A total of six trials was oonduoted in this phase（a nondetailed

each host recorded bites for six consecutive 5 -minute time intervals, there was a total of 480 host-time units in each trial. The number of bites obtained in ea oh of these 480 units was recorded, and the median of these numbers was the so-oalled median bite number. For every time unit, each of the eight squares produced a value--namely, the proportion of hosts in that square with reported bites exceeding the median bite number. Thus, each trial produced 48 proportions.
(U) For each trial, an analysis of variance based on the four-way cross olassifioation of time, host distance, host concentration, and veotor/host ratio was performed on the proportions, weighting each proportion according to the number of hosts involved. In every analysis, the test of significance for each component was made by means of the obi square distribution, the obi square value for each component being obtained in a manner similar to that used in Phase B. The results of these analyses are summarized in Table 5.
(C) As shown in Table 5, the results of the oh square analyses indicated that the difference between the effects of the high and the low veotor/host ratios was highly significant in all trials. Further, host concentration was usually significant, and host distance was signifioant only in Trial c-3. None of the two- or three-way interaction terms, however, showed a tendency for statistical significance. The individual effects of the three host-veotor relationships are discussed below.

## Effect of Veotor/Host Ratio

(U) Table 6 gives the proportions of host-time units which excorded the median bite number in each trial summarized over the two distances and six time units and segregated with respect to veotor/host ratio and the host concentration.
(C) As shown in Table 6, the proportion of host-time units exceding the median bite number was ${ }^{\text {greater, in each comparison, for that }}$ square associated with the higher vector/host ratio (100:1). Further, as shown in Table 7, the data indicate, in general, that when the number of vectors is increased by a factor of 10, approximately 10 times as many bites are received.
(c) Table 7 also shows that the percentage of hosts receiving one or more bites ranged from 40 to 72 per cent, with an average of 60 per cent, when 10 vectors per host were released, and from 95 to 100 per ont with an average of 96 per cent, when 100 vectors per host were released.

## Effect of Host Concentration

(U) Since the higher host concentration squares presented greater bulk and contrast it might be expected that they would be subjected to greater biting activity than the lower host concentration squares. This

| C-6 | 185 | 1735 | 1: 9.4 | 72 | 100 |

was not generally the case in the five trials. In Trials C-1, C-2, and C-3, the lower host conoentration squares exhibited greater biting activity, signifioantly so in Trials C-1 and C-3. In Trials C-5 and C-6, the squares contajning the larger number of hosts exhibited signifioantly greater biting aotivity. As a result of these oontradiotory ifidings, a deoision at this time concerning the effeots of host conoentration on biting aotivity must be deemed premature.

Effeot of Host Distance
(c) As indioated by the results of the ohi-square analyses given in Table 5, only in Trial C-3 were the offeots of host distance upon biting aotivity significantly different. In this trial, however, the actual host distanoes were doubled--the low level from 20 to 40 feet and the high level from 100 to 200 feet. (This ohange was made as a result of the numarous complaints from the host samplers oonoerning the high biting aotivity in the two previously conducted field trials--Trials B-2 and D-2). Thus, the results of these five trials suggest that under the speoific oonditions oncountered there is little difference in the biting aotivity at distanoes up to 100 feet from the release point, but that optimum biting aotivity occurs at distances less than 200 feet. This finding is similar to the finding of Phase $B$.

PHASE D
(c) Indoor biting rate studies at Fort Detriok, Frederiok, Maryland, (4) involving simulated sleoping (sitting), standing, and walking hosts demonstrated that more bites were received indoors as the level of human aotivity decreased. In BELLWETHRR-I, the outdoor biting assessments had all been made with the men seated and relatively motionless. Phase D of BELLNETHER-II was designed to ascertain the effeot of overt movement of the hosts upon the outdoor biting aotivity of this veotor.
(U) In eaoh trial, three groups of three l5-foot radius oiroles; 0.5 mile apart on parallel orosswind lines, were looated and soribed, and 10 hosts were positioned equidistantly along eaoh oiroumference. Conourrent relesses of 100 veotors were made in theloenter of each of the oiroles, and the resultant biting aotivity was assessed. In each line group, the oircles were designated A, B, and C (see Fig. 6). In the A oiroles, the men were seated on the ground and remained relatively motionless. In the $B$ oiroles, the hosts walked around their positions, talked, and otherwise oocupied themselves in motion-assooiated aotivity: In the $C$ oiroles, the hosts were seated for the first 5 minutes, walked, talked, and moved around for the seoond 5 minutes, were seated for the next 5 minutes, and so on unitil the end of the 30 -minute sampling.

Fig. 6. - Grid array for Phase D, BELHWETHRR-II.
(U) The number of bites reoeived in eaoh oonseoutive 5-minute period was recorded by each of the 90 hosts, so that there was a total of 540 host-time units: The number of bites obtained in each of these 540 units was reoorded, and the median of these numbers is the so called medien bite number.
(U) For every time unit, eaoh of the nine oiroles produoed a number-namely, the proportion of hosts on that oirole whose reoorded bites exoeeded the median bite number. An analysis of varianoe based on the twoway oross olassification of time and host aotivity was then performed on the proportions obtained in eaoh trial, and the test of signifioanoe for each oomponent was made by means of the F distribution. The results of these analyses are given in Table 8.

TABL冎 8：Analysis of Variance of Proportions Exceeding Median Bite Number，Trials D－I through D－3，BELLWETHER－II，Bio 531 （CONFIDENTIAL）

160 veotors；consequently，the data obtained at these oiroles were not used in the analysis．
－Degrees of freedom．
${ }^{3}$ Statistically significant at the i．O per cent level．
（U）As shown in Table 8，host activity（H）and its interaction with time（ $\mathrm{H} \times \mathrm{T}$ ）were non－signifioant in all three trials，but time，by itself， was highly significant．For all three trials，vector biting activity was at a maximum in the first time period and steadily declined thereafter． This trend－a decrease in biting activity with an increase in time－－was generally true for all B BLIWETHER－I and－II oirole－type trials．
（C）As compared to the Fort Detriok（4）findings where increased host activity was associated with decreased biting activity，in every one of these three trials host activity，although not statistically significant， showed the C－ciroles（alternating activity－nonaotivity）with the highest and the B－oiroles（continuous motion）with the lowest biting activity． That these results were not statistically significant is perhaps at least partly due to the paucity of oirole replication and the high＂inter－oirole＂ variation．This latter variation may have been induced by meteorological differences from one site to another．（In ea oh trial，the average wind speed difference between the two meteorological stations exceeded 1 mile per hour．）．

## PHASE E

（U）The three trials of Phase $\mathbb{F}$ were conducted to investigate methods of placement of human samplers in a built－up area and to evaluate，in part，
veotor persistency in a desert built-up area. For this phase, 47 stations ${ }^{2}$ in Granite Peak Installation Number 2 (GPI-2) were used. At eaoh station two positions were designated, one near a building, vehiole, or other struoture (Group I) and the other position in an open area 30 foet away from that struoture (Group II). A randomly seleoted host (from the 94 available) was placed at each of the 94 positions so that the hosts were olassified by station and group.
(U) In order to oompare biting aotivity in different seotions of the test area, GPI-2 was somewhat arbitrarily divided into eight sub-areas, as shown in Figure 7. This was acoomplishod using seven groupings of buildings and an additional looation for the parked troop vehicies (Area H).
(U) In each trial, 5000 veotors were released off target at a distance of approximately 100 yards upwind of the nearest building. Release time was either in the early morning or late afternoon and when the temperature was at least $65^{\circ} \mathrm{F}$. Bites received by each host were recorded for eaoh 5minute interval, and sampling was oonduoted from the time of release to the time when biting appreaiably slaokened. In addition, the hosts returned to sample the area during the following one or two orepusouler periods.
(U) Three Phase F trials were oonduoted; however, only one, Trial E-2, generated sufficient data for analysis. In Trial E-1 a oonfusion in regard to the beginning and length of sampling time produoed unreliable data, while, in Trial r-3, anomalously behaving veotors (see DISCUSSION seotion) yielded very few bites, and no meaningiul analysis of the data was possible.
(U) An analysis of varianoe, based on the four-way oross olassifioation of time, area, group, and station (paired Group I and II positions), was performed on the number of bites obtained in Trial E-2, weighting the total number of bites obtained in each area acoording to the number of hosts involved. The results of this analysis are given in Table 9.

## Variability Among Areas

(C) As shown in Table 9, no signifioant differenoe in biting aotivity oould be deteoted among areas. The variance among stations within areas (Error A), however, was quite large, and, consequently, the test of signifioanoe, although appropriate, was not sensitive. ${ }^{3}$ Therefore, biting aotivity among the various areas was empirically examined. Figure 8 shows the average number of bites per host-time unit in Trial $\mathbb{W - 2}$ in eaoh of the
${ }^{2}(U)$ This total was later reduoed to 40 after the oompletion of Trial E-I. This reduotion resulted in removing oertain stations located near the release point where too many bites hed been reoeived (Stations 4, 5, 6, and 7), and at the north meteorological station where no bites had been reported (Stations 1, 2, and 3).
${ }^{3}$ (U) It is not surprising that Error A is large, sinoe the stations within areas were not ohosen as random samples; on the oontrary, hosts were positioned at the expected extremes in order to gain information ooncerning the behavior of the test veotors.

Fig. 7. - Map of GPI-2 area showing sampling stations and areas, Phase $\mathbb{F}$, BELLNETHER-II.

eight areas together with the release point and general wind direotion prevailing during the 70 minutes of initial sampling (see also Figs. 9 through 12). ${ }^{4}$ It may be seen that biting aotivity was greatest in those

[^1]

## 

areas ( $A, B$, and $D$ ) direotly downwind from the release point and decreased with an inorease in orosswind distanoe. Since this was generally true for the later as well as the initial sampling periods, it indicated that the veotors did not distribute themselves evenly throughout the built-up area.
(c) It should be noted that the southeast windflow moved the mosquitoes from the release point successively through Areas $D, B$, and $A$, and that the biting aotivity (average number of bites per host-time unit) inoreased with an inorease in downwind distance. These two faots lend strong support to the oonolusion reaohed in Phase $B$ that intervening hosts do not interfere with the veotor's downind spread.

## Variability Among Stations Within Aroas

(U) Figure 13 illustrates the variability in the total biting aotivity reported among stations (Group I + Group II) within Area B in the initial sampling period. Although other areas showed similar variability, Area B was ohosen since it contained more stations and had more reported bites. In addition, the distribution of bites in Area B, oontrary to that observed in other areas, was unexpeotedly systematic, and it was felt that these data should be partioularly noted.
(c) It may be seen in Figure 13 that the total number of bites obtained at stations in Area B varied considerably, ranging from 0 at Station 15 to 254 at Station 20. Further, the total number of bites obtained at each of the stations in the southern seotion of Area B (Stations 8 through 11 and 19 through 23) was relatively high; while, in oomparison, very few bites were reoorded at stations to the north (Stations 12 through 17). The assumed general wind flow (see Footnote 4, above) probably direoted a majority of the veotors to the southern part of Area B. The presence of the rows of generators on the southern loop road (see Fig. 14) would also oontribute to this. When the veotors reached Area B, the orientation of the buildings may have hindered the spread of the veotors to the northern stations. However, other faotors, suoh as flight in the orosswind direotion, terrain slope, host density, or a oombination of these or other faotors might equally explain the results. Therefore, at present, the exaot reason for the observed laok of uniformity in the distribution of bites throughout the area is not known.

## Effeot of Position (Group I versus Group II)

(c) The results of the analysis of varianoe (Table 9) indioated that there was a significant difference between the number of bites obtained at positions looated near struotures (Group I) and those located in open areas (Group II). Table 10 shows that the average number of bites per host-time unit was approximately twice as large for the Group I as for the Group II positions (Column 17 and 18); however, the magnitude of the differenoe changed significantly with area. If the areas where higher biting occurred are examined (Areas A, B, and D), it may be seen that in Area A approximately three times as many bites were obtained at Group I positions

Variability Among Stations
(U) From an empirioal examination of the various stations, it was evident that there existed considerable differences among them, and, moreover, it was not reasonable to expect similar biting aotivity. Two important differences in stations were:

1. The station location in relation to the release point and the general wind flow, and
2. The amount of proteotion from the wind that the building offered to the mosquitoes.

These differences are depioted, in part, by the seleoted stations shown in Figures 15 through 19.
(C) Station 20 (Fig. 15) was located near and downwind from the release point, while Stations 33 and 34 (Fig. 16) and Stations 47 and 48 (Fig. 17) were looated at both greater distances and orosswind from the release point. A total of 254 bites was recorded at Station 20 as compared to $0,0,3$, and 0 bites at Stations $33,34,47$, and 48, respeotively. This illustrates a general observation of Trial a-2-namely, that high vector biting aotivity was usually found only near and/or downwind from the release point.
(C) Station 24 (Fig. 18) was looatod downwind and at a distanoe approximately twioe as far from the release point as were Stations 33 and 34 ( $F i \mathrm{~g}$. 16). A total of 113 bites was obtained at Station 24. Comparing this result with the results obtained at Stations 33 and 34 illustrates the general finding that, under the oonditions of this trial, veotor biting aotivity had a higher correlation with downwind location than with distance from the release point. It should also be noted that Station 24 was approximately 1400 feet from the release point, an effeotive distance considerably greater than one would expect from examining the Phase $B$ and $C$ data.
(C) A total of 79 bites was obtained at Station 37, 75 of whioh were reooived at the position near the building. This comparison indicates that alcoves (see Fig. 19) offering shelter from the wind are highly attraotive to the vectors. In support of this view, it may also be pointed out that at the remaining six stations of Area $G$, possessing no alcoves, an average of only 23 bites per station was obtained.

Rosults of the Seoond Crepusoular Period of Trial E-2
(U) In the morning (4 Ootober 1960) following the evening veotor release of Trial E-2, the troops retumed to their assigned positions in the GPI-2 area. Bites reoeived by each host were reoorded for each 5 -minute interval, and sampling was conducted from 0630 to 0830 MST and from 0920 to 1000 MST .

(UNCLASSIETSD)

(C) Only one bite was obtained throughout the test area from 0630 to $0800 \mathrm{MST} ; ~ h o w e v e r, ~ d u r i n g ~ t h i s ~ t i m e, ~ t h e ~ a i r ~ t e m p e r a t u r e s ~ r e c o r d e d ~$ at 0.5 meter averaged only $53.2^{\circ} \mathrm{F}$. From 0800 to 0830 MST ; the temperature increased to an average of $59.2^{\circ} \mathrm{F}$, and in this interval a total of 25 bites was recorded.
(C) From 0920 to 1000 MST , with an average temperature of $72.6^{\circ} \mathrm{F}$, a totel of 128 bites was obtained. These results, segregated with respeot to time and group, are presented in Table 12.

TABLE 12: Biting Results Obtained from 0920 to 1000 MST Segregated With Respeot to Time and Group, Trisl $\mathrm{H}-2$, BELWETHIRR-II, Bio 531 (CONITIDENIIAL)

| $\begin{aligned} & \text { TIMEB INTERVAL } \\ & \text { (MST) } \end{aligned}$ | TOTAL NUMBER OF BITHS PER INDICATRD GROUP |  | TOTAL NUMBER OF BIIES |
| :---: | :---: | :---: | :---: |
|  | Group I | Group II |  |
| 0920-0925 | 13 | 4 | 17 |
| 0925-0930 | 4 | 7 | 21 |
| 0930-0935 | 13 | 12 | 25 |
| 0935-0940 | 15 | 4 | 19 |
| 09 40-0945 | 11 | 4 | 15 |

| 0955-1000 | 8 | 3 | 11 |
| TOTAL | 91 | 37 | 128 |

(U) As a result of comparing this low vector biting aotivity with that obtained during the previous crepusoular period, sampling was terminated at 1000 MST and was not reinstituted that evening.

## PHASE F

(C) The purpose of the Phase Frials was to determine the average longevity of the A. aegypti mosquito when exposed to ambient desert conditions. To answer this objective, four l00-veotor exposure cage cones, two containing guinea-pig-fed mosquitoes and two with starved mosquitoes, were exposed to ambient desert conditions at ground level. One cage of guinea-pig-fed and one of starved vectors were placed in relatively dense, indigenous vegetation; the other two cages were positioned in the open nearby. Observations were to be made as to the total number of survivors at the end of each hour for a period of 24 hours or until at least 50 per cent of the vectors had died. Four trials were originally scheduled. These trials were conducted near Baker Laboratory under the direotion of the Test Officer.
(U) Two Phase $F$ trials were oompleted, both of whioh were subsequently classified as aborts. This resulted primarily beoause 100 veotors proved to be too large a number in one cage for adequately olassifying them as to either dead or alive without removing the dead from the oage. In attempting to remove the dead mosquitoes from the oage, the procedure followed was to invert the oone, thereby shaking the dead into the oap and (hopefully) inducing the live ones to fiy to the upper parts of the oone. However, a number of live vectors remained in the oap area and escaped when it was removed. As a result, it was impossible to determine the peroontage of veotors surviving.

## DISCUSSION

(c) BELLMETHRR-II was oonduoted primarily to develop a field test teohnology that would be useful for the testing of various arthropod veotor systems. Approximately 100 military personnel from the 45 th and 46th Chemioal Companies of the and Chemioal Battalion (Smoke Generator) were assigned to be samplers in these trials. The laok of seourity olearanoe for the military personnel posed a diffioult situation. The men oould not be expeoted to perform their tasks to the best of their ability when the test design did not make sense to them; yot the purposes of these prooedures oould not safely be made meaningful to uncleared personnel.
(v) Other field test teohnology problems that developed in BELWETHERII included meteorological instrumentation and laboratory prooedures.
(U) The meteorologioal stations were both too few and too far away from the points of primary interest--the oenters of the oiroles, squares, and areas. The meteorologioal stations had been moved away from the testing network to prevent their buik and personnel from distorting the test results. During periods of large-soale weather phenomena--i.e., pre- and post-frontal passages, strong low pressure systems looated olose by, eto.-the wind movements are relatively steady and olose-in meteorologioal support is not oritioal. However, the requirements for low wind speeds in field testing mosquitoes would usually rule out general, steady wind flows; therefore, light winds, variable in both speed and direotion, are the rule. Sinoe mosquitoes have been found to be so extremely sensitive to winds (see 2), only data releoting the variable wind movements to whioh the veotors are aotually exposed will yield information resolving muoh of the variability oocurring between trials. Beoause of the imperative need for reduoing the exoessive trial-to-trial variability, it is neoessary that close-in meteorological support be furnished for future fiold trials.
(U) The second problem was laboratory control. The general prooedures followed for rearing the test veotors used in the DPG tests have been for Baker Laboratory to grow the mosquitoes fromegg papers furnished by Biolabs. When a batch of larvae reaohed the pupal stage, the sexes were separated and female pupae were oounted out into $10 \theta$ oream oartons of
a size dependent upon the partioular trial for whioh they were soheduled. Here they were held, fed when necessary, and then used in the various trials. The veotors were required to be 6 to 10 days of age (as adults) and starved for 12 to 24 hours prior to use.
(U) Under the belief that these general laboratory procedures would yield a standard produot, no speoifio laboretory controls were made. However, cortain anomalous veotor behavior situations were observed during the oourse of BMLHETHRR-II. In Trial B-3, those mosquitoes released at the oenter of the single 250-foot oirole failed to reach the periphery. Although this probably could have been resolved by having the men; at the end of the trial, move in toward the oenter noting where the mosquitoes were, it was not done. In Irial $\mathrm{f}-3$, the veotors stayed in a ball on the ground at the release point; they were alive but failed to move out. (A footnote to Table XX of Teohnioal Study 7B (4) states that, on a 40mosquito release, "l2 mosquitoes did not leave the floor." This oould be the same phenomenon.) The reasons for this anomalous behavior oould probably have been ascertained had laboratory oontrol batohes of the same lots of vectors been maintained and observed in the inseotary. Since these behavioral anomalies could have developed anywhere from variations in egg papers to the environment imendiately before the trial, tighter laboratory controls are an obvious neoessity and will be implemented in future testing. In addition, sample batohes will also be transported to the field, and, although they will not be released, they will be exposed to the same ambient conditions as the test lots. After the oompletion of the trial, these will be returned to the inseotary and observed. Complete reoords will be kept on all batches and lots. It has proved impossible to $f$ ind any logical reason for the greatly enhanced biting inourred in Trial B-2 (see Table l), and more oomprehensive laboratory control work might possibly have shown the reason(s).
(c) The mosquitoes used in BELLWHTHER-I and -II were reared in an insectary having an $82^{\circ} \mathrm{F}$ temperature and a relative humidity of 80 per oent. While these conditions are ideal for a tropical mosquito soheduled for release under tropioal conditions, the sudden ohange to ambient desert conditions of often widely differing temperatures and muoh lower humidities might constitute a shock to the mosquito's physiological systom. Therefore, pre-trial temperature oonditioning will be investigated prior to and in future testing.
(U) Parker (5), oomenting on the observed differences in the mosquito responses to dry and moist surfaces at different temperatures as contrastingly reported both by him and by Christophers (6), suggests that the subsequent mosquito behavioral patterns were more dependent on the temperature-humidity oonditions during rearing and holding than were generally realized. In both investigations the inseots had been exposed from, or very nearly from, the time of emergence to the temperatures and humidities at which the experiments were later performed: Parker's at $82.4^{\circ} \mathrm{F}\left(28^{\circ} \mathrm{C}\right)$ and 50 to 70 per cent relative humidity and Christophers' at $77.0^{\circ} \mathrm{F}\left(25^{\circ} \mathrm{C}\right)$ and 80 to 90 per oent relative humidity. Parker further suggests that a temperature-humidity differenoe operating before an experiment can so condition the females as to produce the same type of difference in response as can a similar temperature and humidity differenoe operating during the
experiment. These thoughts strongly indioate a further need for additional laboratory work to asoertain the optimum rearing-holding oonditions for different environmental releases.

## CONCLUSIONS

(S) From the data generated in BRLLMETHRR-II, and under the speoific conditions encountered, it is conoluded that:

1. In a 30 -minute sampling period, there was no signifioant differenoe in veotor biting aotivity at distanoes up to 100 feet from the release point, but maximum biting aotivity oocurred at distanoes less than 200 feet.
2. Intervening hosts did not interfere with either the veotor's outward spread or biting aotivity.
3. No conolusive findings were generated as to the effeot of host conoentration.
4. When the number of veotors was increased by a faotor of 10, approximately 10 times as many bites were reoeived and the proportion of hosts bitten was inoreased an average of 36 per oent.
5. Veotor biting aotivity showed a tendenoy to be highest When the hosts were alternately in motion and then motionless for recurring 5-minute periods, end to be lowest when the hosts moved oontinuously.
6. Hosts looated near buildings were subjeoted to signifioantly greater veotor biting aotivity than were hosts located in open areas.
7. Veotors did not tend to distribute themselves evenly throughout an isolated built-up area and, further, they did not tend to redistribute themselves evenly during the interims between host oocupations.
8. No conclusive findings were generated as to the optimum sampling duration.
9. No evidenoe of orepusoular-period biting preference was obtained in these trials.
10. No conclusive findings were generated conoerning the average Iongevity of this speoies when exposed to ambient desert conditions.

[^0]:    ${ }^{I}(U)$ From an examination of the raw data, it was evident that the assumptions required for the standard methods of analysis were not satisfied. Further, the appropriate transformation of the data could not be made since the form of the distribution of bites was unknown. Therefore, the above-desoribed distribution-free analysis was used instead. Standard analytical data such as bite means, their standard deviations, eto., tabulated for unit time intervals, are presented in Appendix B.

[^1]:    ${ }^{4}(\mathrm{U})$ The direotion of wind flow in the GPI-2 area during Trial E-2 perhaps needs further elucidation, GPI-2 lies in the mouth of the canyon whioh contained the southernmost of the two meteorological stations. This station was located near the water tank (see Figs. 9-12). At this station the winds reparted were generally southwest. The other station was situated on the flattening slope in the open 0.5 mile to the north of the area, and there the winds were generally southeast. An assumed southeast wind flow for the built-up area in the oanyon mouth was made for several reasons. The presence of two side canyons, with the larger one oriented south-west-to-northeast (see Figs, 9 and 12), could acoount for the southwest winds reported at the south meteorologioal station. The fact that the south-to-north extending upper canyon with its sharply rising walls would be in shadow earlier than the mouth would most probably result in a downflowing of relatively cool, dense air. This underiding, downflowing dense air would be subjeoted to a westward deflection both by the ourving ridge of rock at the canjon mouth (see Figs. 9, 10, and il) and by the general southeast windflow. Finally, this defleoted air would be given a northerly impetus when it reached the western oanyon wall, bringing it past station 24. The observed pattern of mosquito movement would further support this belief that the actual wind flow pattern in the built-up area was southeast to northwest. The known need for olose-in meteorologioal support in entomological field testing was clearly evidenoed in this phase.
